

V. Sobolev, although many of the results presented also can be obtained by Case's method (see K. M. Case and P. F. Zweifel, *Linear Transport Theory*, Addison-Wesley, 1967). Considerable space is given to research carried out in recent years at the University of Lenin-grad. The book stands as the definitive current reference for analytical line transfer solutions based on the two-level atomic model.

Similar problems are treated by computational methods in a recent book by R. G. Athay, *Radiation Transport in Spectral Lines* (Reidel, 1972). Related physical applications are discussed by J. T. Jefferies, *Spectral Line Formation* (Blaisdell, 1968) and D. Mihalas, *Stellar Atmospheres* (Freeman, 1970).

The translation by Eileen Weppner and D. G. Hummer is an excellent one, and reflects Hummer's complete knowledge of the subject and his familiarity with Ivanov's published work. The material should be of interest to those who study the theory of neutron diffusion as well as those who deal with radiative transfer theory.

Martin Harwit
561 pp. Wiley, New York,
1973. \$14.95

This is a book I would like to have my students read, particularly those whose background in physics has been weak or highly specialized. It gives a broad panorama of what might be called the physics of modern astronomy. Martin Harwit treats topics from the point of view of the physical principles believed to be involved rather than according to conventional dichotomies as to subject matter. Hence surprising juxtapositions of topics, such as galaxies and molecules, sometimes appear.

Discussion of modern developments does not crowd out classical subjects. Harwit's style in dealing with physical principles is lucid and clear, and he is to be commended for patiently explaining steps in derivations that are often glossed over or regarded as patently obvious by less skilled teachers. A nice feature of this treatment is the excellent set of problems, the solutions of which are given in the text. The material will be of great help to the student who likes to dig things out on his own. To a large extent the basic physics so necessary to modern astronomy is developed *Ab initio*.

It is unfortunate that important topics like synchrotron radiation could not have been developed in a more thor-

MATERIALS RESEARCH CENTER REPORTS . . .

On a new Raman
spectrometer
for remote
gas analysis.

At the Materials Research Center, Dr. J. J. Barrett has been investigating methods for the remote analysis of gases at low concentrations (ppm). These studies have led to the development of an instrument system that sensitively measures light which has been scattered from a gas by the rotational-Raman effect.

The Barrett Spectrometer is applicable to the detection and analysis of gases at a point remote (km range) from the instrumentation; this is of obvious value in studies of air pollutants. It efficiently detects natural CO_2 in air and scattering has also been observed from SO_2 , C_6H_6 , CO , NO , N_2O and HCl molecules. The system is useful as well in measuring the gas temperatures because it can measure the temperature dependence of the ratio of the Stokes to the anti-Stokes scattering intensity.

Conventional remote Raman spectrometers are limited by the relatively low intensity of vibrational-Raman scattered light and by low luminous transmission. These limitations are largely overcome by the new instrumentation; its sensitivity, for example, is 10^3 to 10^4 greater. This improved sensitivity together with high resolution is achieved through the ability of the system's unique Fabry-Perot interferometer to integrate optically all of the Raman lines in a band. (An essential part of the Barrett system is a wide-range scanning Fabry-Perot interferometer. This device appears to have marked advantages for various uses in addition to its present use in the new spectrometer.)

Compared to conventional Raman spectrometers, the Barrett system has three major advantages: (1) the larger rotational scattering cross section of a molecule is used; (2) all of the rotational Raman lines in a band are integrated to form the sum of the signals from the individual scattered rotational lines; (3) instrumental luminosity is as much as 100 times that of a conventional spectrometer.

The Materials Research Center work on detecting and measuring atmospheric species and pollutants is continuing as are other Raman-effect investigations.

We've got the tools....

for light measurement.

All the Basic Tools. Tools that can be used in a number of ways. And every EG&G tool is the finest available anywhere at any price.

Here's how the idea works for you. Start with a detector head which determines light sensitivity and spectral range, and an indicator unit for reading results. These are basic tools.

Add a hooded filter holder that blocks out off-axis light and you have the Model 580 Radiometer. It measures visible, IR-visible or UV-visible light, continuous and pulsed (to 1ns) depending on the detector head you choose.

Drop a photometric filter in the hooded filter holder and it's a Photometer.

Add a power supply and change to a high sensitivity detector head, and suddenly it's a high sensitivity Radiometer.

Add beam input optics and a grating monochromator, and the Model 580 Radiometer becomes a Model 580/585 Spectroradiometer. And you can go even further. To a high sensitivity or IR Spectroradiometer if that's what the job requires.

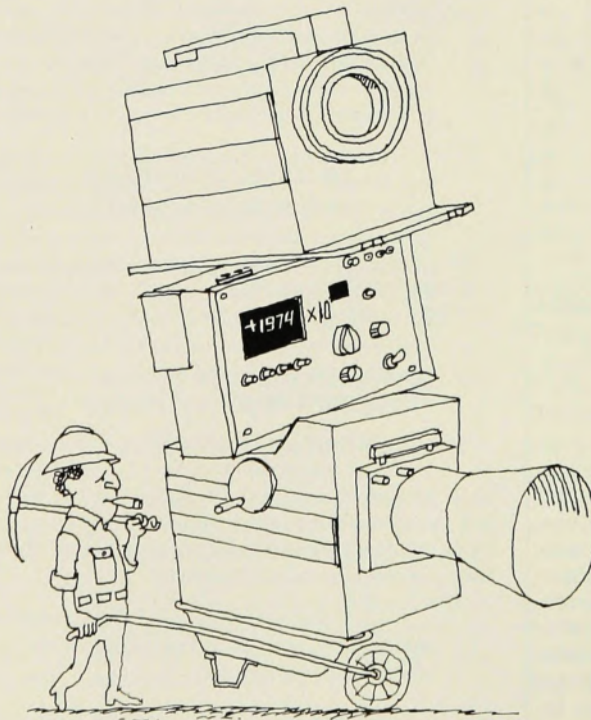

It's as simple as that. You build your own system. Make it as sophisticated or as simple as you need.

Basic tools. It's really quite an idea. Especially when you consider our newest tool, the Model 580-13 indicator unit with features like auto-ranging over seven full decades (which makes it totally computer compatible); and an ambient light compensation system so you don't have to take your measurements in a closet.

The EG&G line boasts a host of accessories, like microscope and telescope adapters, fiber optic probes, narrow beam adapters, and laser samplers.

EG&G. We've got the tools. The right tools.

ough way—perhaps at the cost of simply quoting results of the two-body problem whose development now appears in many beginning physics texts. In attempting to cover such a broad spectrum of subject matter, embracing so much of physics and astronomy in a mere 500 pages, it is inevitable that some topics are handled in an inadequate or frustrating fashion. The student first should read a good elementary text such as George Abell's *Exploration of the Universe*. Chapter 2 could have been deleted. Likewise, the discussion of stellar atmospheres and spectral line formation cannot be recommended. The value of the text would have been greatly enhanced by a careful set of reading guides to significant references including review articles and monographs. While references to original literature are to be commended, documentation of a minor interpolation formula can scarcely substitute for mention of truly fundamental work by the same author.

It is unfortunate that the most engaging problems posed by the nearest star, the Sun, are scarcely even mentioned. Only in certain solar flares can we actually witness the origin of cosmic rays and obtain an insight in what may be expected in the outer envelopes of other normal stars. The speculations on tachyons could easily have been sacrificed to provide space for these really basic topics.

In summary, Harwit is to be congratulated on producing a worthwhile contribution to the astrophysical literature.

DEPARTMENT OF PHYSICS

Applications are invited for a one year position of a visiting (full-) professor, who has experience in one of the experimental research fields represented in the department: solid state physics, atomic and molecular physics, high energy physics and biophysics.

Applicants are expected to commence duties in September 1976.

Applications, including a curriculum vitae, an account of professional experience and publications, and the names of two referees should be sent to

Prof. Dr. R. T. Van de Walle, Faculty of Science, Toernooiveld, Nijmegen, Netherlands, where further information concerning the post and the department may be obtained. The application- deadline is August 1ste. 1975.

DIRECTOR PHYSICS DIVISION

Argonne National Laboratory

Applications and nominations are invited for the position of Director of the Physics Division of Argonne National Laboratory. The Division conducts broad-ranging research in nuclear and atomic physics. Nuclear physics work, carried out in medium-energy, low-energy and theoretical programs, seeks to gain an understanding of basic nuclear phenomena and to obtain important nuclear data. Atomic physics activities strive to understand atomic, molecular and ionic structure, radiations and reactions, many of which are of long-range importance in energy generation. A candidate should have a distinguished record of achievement in areas of physics relevant to the Division's programs. He or she should have the ability to provide sound, imaginative leadership to the Division and the motivation to contribute to decision-making in a large and diverse Laboratory. Argonne is operated by the University of Chicago under a contract between the University of Chicago, the Argonne Universities Association, and the United States Energy Research and Development Administration.

Applications or nominations should be submitted by May 1, 1975, to Dr. Robert G. Sachs, Director, Argonne National Laboratory, Argonne, Illinois 60439.
